FATIGUE LIMIT STATE IN SAFI HSE

The SAFI HSE software includes the fatigue limit states.

Here are some highlights about fatigue in the HSE software.

Highway Sign Wizard

A step has been added into the highway sign wizard so all fatigue parameters for the structure can be set here. The CAFT (Constant Amplitude Fatigue Threshold) or $(\Delta F)_{TH}$ for infinite life for the different fatigue detail categories are found in AASHTO LTS-13 (ASD) Table 11.9.3.1-1 and AASHTO LTS-15 (LRFD) Table 11.9.3.1-1.

If you click on the **Default** button the $(\Delta F)_{TH}$ values will be set to typical values for the different connection details based on the AASHTO. These value **must be validated** by the user since some of the $(\Delta F)_{TH}$ depends on the connection details which are not known precisely by the program. The AASHTO LTS-13 (ASD) Cl. 11.9.3.1 and AASHTO LTS-15 (LRFD) Cl. 11.9.3.1 provide full information to compute $(\Delta F)_{TH}$.

The typical connection details for this structure are shown below:

| **Unaltered metal/Away from connection detail**	**Beam: Beam seat**
Beam: Diagonal attached to a beam chord $\Delta\sigma_{(1)}$ **Beam: Beam chord at a diagonal attach** $\Delta\sigma_{(2)}$	**Column: Diagonal attached to a support chord** $\Delta\sigma_{(1)}$ **Column: Support chord at a diagonal attach** $\Delta\sigma_{(2)}$
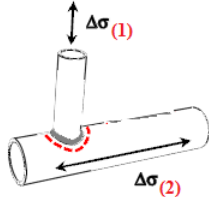

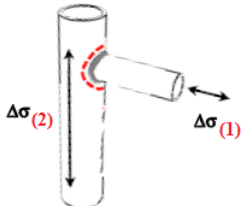

Beam: Beam splice plate	Column: Support chord at a base plate Column: Pedestal splice plate

Editing Fatigue Parameters

The **Highway Sign Wizard** auto assign these values when generating the model according to the input data. If the model has not been generated or after the model generation is done, the user can edit this table to change the fatigue parameters for the connection details for both ends of the member. This command is available only for AASHTO LTS et S6 code.
This main option activates the input required for fatigue verification. Depending on the type of structures, the fatigue verifications (Galloping, Natural Wind Gust, Truck-Induced Gust) may be activated or not. The user have to check on the applicable fatigue loads according to its type of structure based on the requirements of the AASHTO LTS code.

Enable Galloping

Galloping results in large amplitude, resonant oscillations in a plane perpendicular to the direction of the wind. It is generally limited to sign/signal mast arms with attachments to the arm. Galloping is typically not caused by the support members, but rather by the attachments to the horizontal mast arms. Therefore, structures without attachments are not susceptible to galloping induced wind load effects.

The galloping force is based on the frontal projected area of each sign panel, traffic signal head including back plate, and all other devices attached to the mast arm. The galloping force is **not** applied to the projected area of the arm or the pole members. The galloping force is applied in the vertical direction.

The software applies the galloping force for all sign panels at the same time. In case of cantilever arms both sides of an individual vertical support, this procedure is not adequate.

Please refer to AASHTO LTS-13 ASD clause 11.7.1.1 or AASHTO LTS-15 LRFD art 11.7.1.1 for more information.
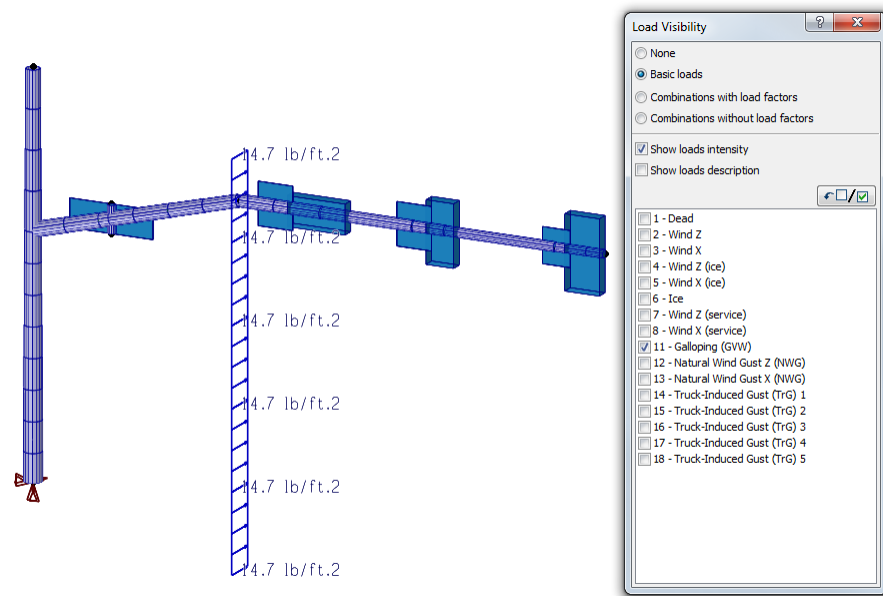

Enable Natural Wind Gust

Natural wind gust stresses result from the inherent variability in the direction and velocity of the wind induced airflow around the structure. Natural wind gusts are the most basic phenomena that may induce cyclic loads in lighting and traffic structures. It is generally applied to cantilevered and non-cantilevered overhead sign and overhead traffic signal supports.

The Natural Wind Gust is applied in the horizontal direction for all wind directions.

Please refer to AASHTO LTS-13 ASD clause 11.7.1.2 or AASHTO LTS-15 LRFD art 11.7.1.2 for more information.
Enable Truck-Induced Gust

Truck-induced gust loads are caused by the passage of trucks under traffic structures. These gusts of wind are caused by moving trucks and create both horizontal and vertical pressure on the structure. The vertical mast arm vibration results in the most critical stresses and therefore only the vertical pressures are evaluated. It is generally applied to cantilevered and non-cantilevered overhead sign and overhead traffic signal supports.

The truck gust force should be applied in the vertical direction, to the horizontal plane (bottom projected area), along any 12' length of the mast arm. The pressure shall also be applied to the horizontal area of each traffic signal head, sign panel, and all other devices located within that 12' length of the mast arm, to create the maximum stress range.

Please refer to AASHTO LTS-13 ASD clause 11.7.1.3 or AASHTO LTS-15 LRFD art 11.7.1.3 for more information.
Fatigue Load Combinations

The fatigue limit state is the ratio of the axial stress range (Δf) due to fatigue load divided by the allowable stress range (ΔF)$_{TH}$. It is computed only for **Fatigue** load combinations.

Fatigue Limit States Results

The following image corresponds to the fatigue limit state for the worse load combination.
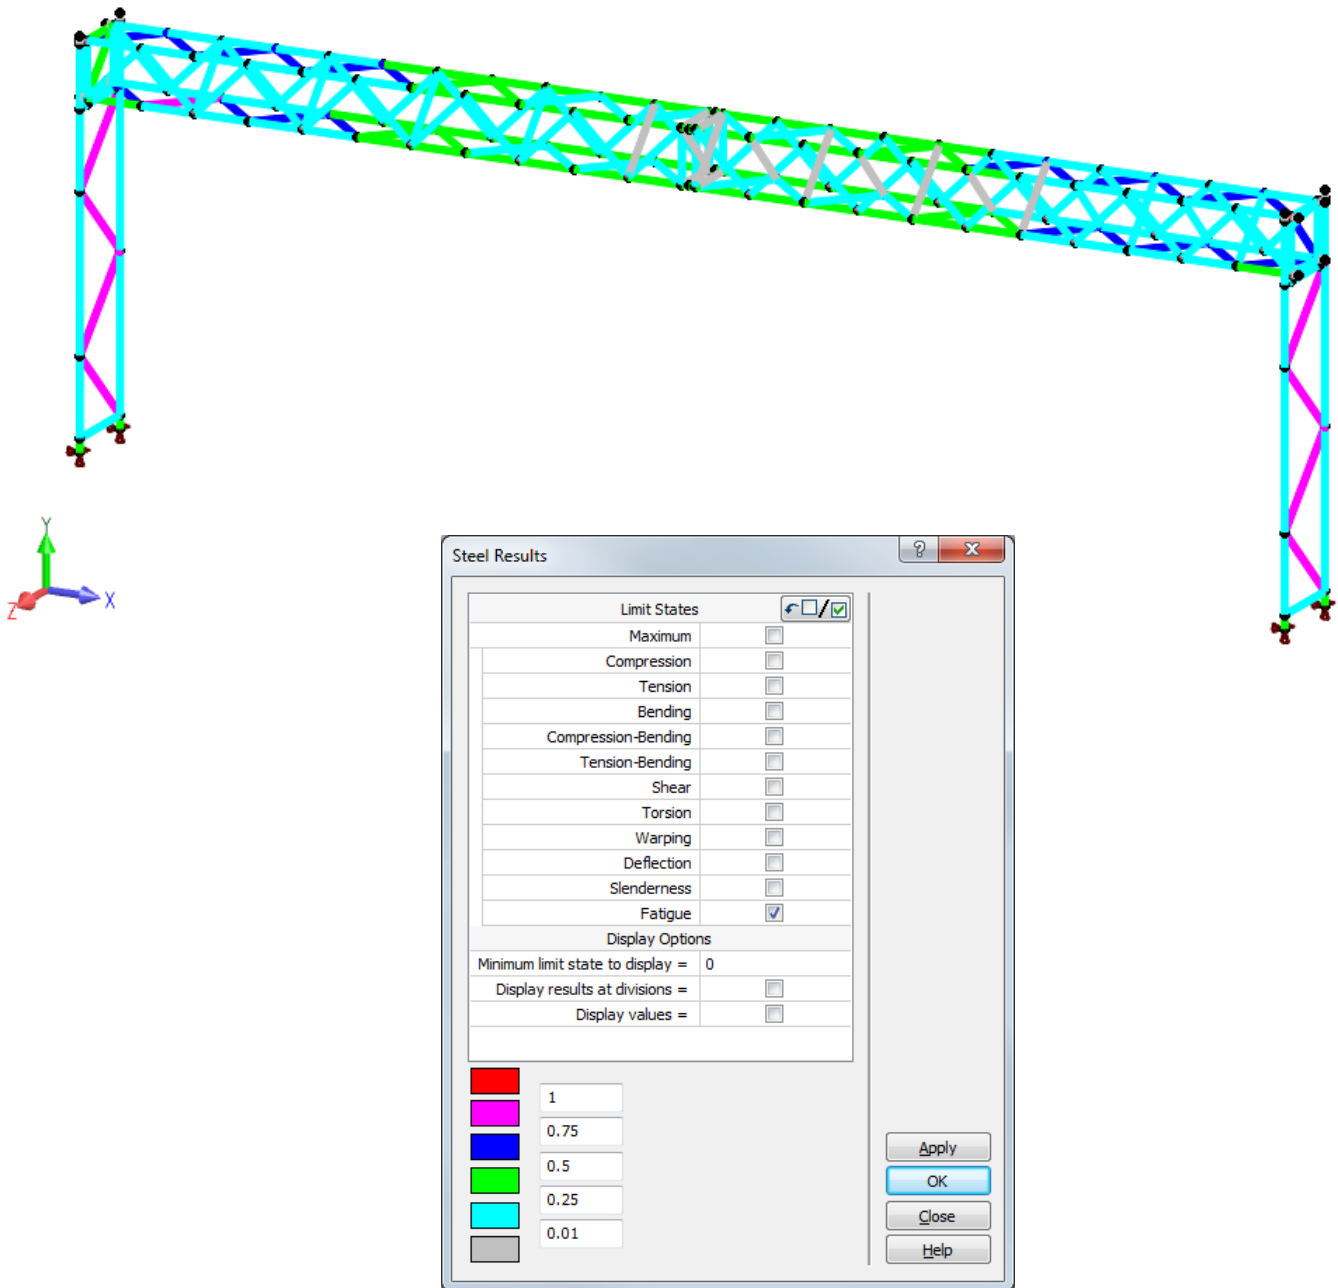

Limit states at divisions allows to see the fatigue limit states at both ends and along the member, as shown below.

The fatigue limit state is the ratio of the axial stress range (Δf) due to fatigue load divided by the allowable stress range $(\Delta F)_{TH}$. These values can be verify at member Joint I and J, as well as along the member.

Fatigue Limit State

Anchor Rods

The command **Highway Sign Anchorages** allows to define the input data for the anchorages.
The anchorage resistances and limit states are computed according to the following clauses according to the selected standard.

- AASHTO LTS-15 (LRFD) clause 5.16.3
- AASHTO LTS-13 (ASD) clauses 5.17.4.1 to 5.17.4.3
-

The fatigue verification for the anchorage rods is also computed according to the specified allowable stress range $(\Delta F)_{TH}$.
